Administrivia

- Reminder: Homework 1 code due today. A little more in class; office hours this afternoon if you have last-minute questions.
- Homework 2 due dates posted. Design due next Thursday.

Slide 1

 Reminder: Quiz 1 Tuesday. Quizzes will be ten minutes at end of class. Open book, open notes, okay to browse (on Web) course material and Java library API. Anything covered in class or in reading is fair game. Only worth 10 points, so not something to stress about!

JAR Files

 Recall discussion from a previous class about differences between Java and C with regard to compiling, linking, and executing — Java source code compiled to byte code, no linking step (such as is done for C), instead byte code for all classes loaded at runtime by the JVM.

Slide 2

- Where does the JVM find needed byte code? via "class path" which can include
 - Directories/folders, such as the one(s) containing byte code for your classes — look for .class files.
 - "JAR (Java Archive)" files, which can contain byte code for many classes.

Adding a JAR file to the default class path is a little like adding a flag such as -1m when you compile a C program.

CSCI 1321 September 18, 2008

Homework 1 Clarification(s)

- Far from unusual for students to feel a little lost at this point so try on your own, then ask!
- Method instance in BasicGameSetup mentions "singleton". What's that about? Reference to "singleton design pattern" idea that for some classes there should only ever be one instance.

Slide 3

Arrays in Java

- Arrays are objects unlike in C/C++, where they're basically pointers.
- Declaring (references to) arrays denote by putting brackets after type.
- Creating arrays use new, e.g.,

new int[10]

new String[n]

(Remember that the second one only creates references.)

- All arrays have length variable.
- Otherwise, syntax is same as C/C++; indices start at 0.
- Java runtime does automatic bounds-checking unlike in C/C++, get "exception" rather than random problems.

Slide 4

Multidimensional Arrays

• "Arrays of arrays", e.g.,

int[][] x = new int[10][100]; declares an array of 10 arrays of 100 ints.

• Reference elements with row, column indices, e.g.,

```
x[row][col] = 10;
```

• Both dimensions accessible:

```
x.length = ?
x[0].length = ?
```

Strings in Java

- In C, "strings" are just arrays of characters, terminated by null character.
 Simple, but many potential problems (such as trying to read more characters from input than will fit into allocated space).
- $\bullet\,$ In Java, there's a library class, String.

• To see what's available, look at the API . . .

Slide 5

Slide 6

String Class, Continued

- In general, no operator overloading in Java, with one exception "+" for strings. Non-string objects converted using (their) toString method. Primitives converted in the "obvious" way.
- To compare two strings, "==" is rarely what you want. Instead, use equals.

Slide 7

- Strings are "immutable" once created, can't be changed. (Why? allows them to be safely shared.) Methods you would think might change the value return a new string.
- Use StringBuffer if you need something you can change, or for efficiency.
- Let's do some examples . . .

Sidebar — Immutable Objects

- String is an example of a class that's "immutable" once created, objects
 can't be changed. If you look at the API for String, you notice that
 methods that "change" the string actually return a new one.
- Slide 8
- This sounds inconvenient, right? What advantages might it have?
 (Remember that "object" variables in Java are really references. So two variables may both refer to the same object.)

Minute Essay

- Write code to define an array of four Strings and fill it with data of your choice.
- Write code to define a two-by-three array of int and set each element to the sum of its row and column.

Slide 9

• If I declare an array of MyClass references:

```
MyClass[] objs = new MyClass[10];
do all the elements of objs have to be instances of MyClass, or can they
be instances of some other class?
```

Minute Essay Answer

• One solution (array of Strings):

```
String[] s = new String[4];
s[0] = "hello";
/* other three lines similar */
```

Slide 10

• One solution (array of ints):

```
int[][] a = new int[2][3];
for (int row = 0; row < a.length; ++row)
    for (int col = 0; col < a[0].length; ++col)
        a[row][col] = row + col;</pre>
```

 Elements of an array declared as MyClass[] can be instances of any "subtype" of MyClass — MyClass itself, or any subclasses. (Trick question!)
