• Slides from class will be on Web — preliminary version shortly before class, final version later that day.

Slide 1

Java Basics — Recap

- Java programs consist of classes. Each class can contain
 - Variables instance and static.
 - Methods instance and static.
 - Classes (more about this later).

ide 2 Notice that each source-code file can contain at most one public class.

- \bullet Variables and methods can be ${\tt public}$ or ${\tt private}.$
- Variables and methods can be final. (Use static final for constants.)

Java Syntax

 Basic syntax based on C — variable declarations, method definitions, expressions — with some additions (as discussed in class and in the text).

• (This was by design.)

Slide 3

Variable Types

- Primitive types provided for efficiency (not purely object-oriented):
 - boolean, short, int, long, float, double are pretty much as in C.
 - char is 16-bit Unicode.
 - byte is 8-bit byte.
- All other variables are *references to objects*, similar to pointers:
 - ${\tt MyClass}\,$ x creates a $\it reference,$ not an object use ${\tt new}$ to create objects.
 - Type of x is MyClass (just as type of an int variable is int).
 - Value of null means it doesn't point to anything.

Variable Scope

- As in C, variables have "scope" (region of the program in which they're valid), but possibilities are somewhat different:
- Instance variables data for object, can be used in any method.
- Class variables data for class (one copy for all objects), can be used in any method.
- Local variables declared within a method or block, only valid within that
 method or block. Notice also that you can declare variables anywhere, not
 just at start of method.
- Advice: Use narrowest scope that will work.

Creating Objects

 \bullet Create object of class ${\tt MyClass}$ using ${\tt new}$ operator, e.g.,

MyClass x = new MyClass();

This object contains its own copy of all instance variables defined in ${\tt MyClass}.$

 new above invokes a constructor for MyClass — method with no return type. Can have any number of these, with zero or more parameters. If none is supplied, compiler generates one with zero parameters. Useful for setting

initial values for variables.

Slide 5

Deleting Objects

• No need to explicitly free/delete objects — Java has "garbage collection".

• (Contrast with C, where you must free dynamically-allocated memory yourself.)

Slide 7

Referencing Objects, Variables, and Methods

- Within MyClass, reference members of class (variables and methods)
 using just their names. If you have multiple objects of this class, which one is
 meant? "current object".
- In code using MyClass, reference as, e.g., x.foo(parameters) for instance methods, and MyClass.staticFoo(parameters) for static methods.

Similar syntax for variables, but likely to be used less, since variables are normally private. (Exception is constants.)

Passing Parameters

- Syntax is like C.
- Everything is passed by value but for reference variables, copying just creates two pointers to the same object, and the called method can change the object.

Slide 9

(More about this later.)

Comments

- Can use C-style comments, C++-style comments.
- One type of C-style comments are special "documentation comments" or "Javadoc comments". These start with /** and end with */, and the command-line tool javadoc turns them into HTML documentation similar to what Sun provides for the library functions. (IDEs, Eclipse among them, also have a way to do this.)

Slide 10

 Use documentation comments to describe what people using your class need to know. Use other types of comments to document code itself — something that would be useful to humans reading it.

Java Basics, Continued — Control Structures

 Most control structures are the same as C — if, while, do, switch, for, etc. Also a simplified for, as of Java 5.0 (a.k.a. 1.5), called "for-each".
 More about it later.

Slide 11

 Also have "exceptions" — a way to deal with unusual or error conditions, break out of current flow of control. Can be "thrown" and "caught" (or not caught, in which case the program crashes). More about them later.

Example

- Example Account class.
- (This example, and most other code from class, will be on the Web, linked from the "Sample programs" page (here).)

Minute Essay

Make your best try at writing a method for our Account class that computes
one month's interest and adds it to the balance. Assume you have a instance
variable interestRate of type double containing the monthly interest.
 (For minute essays where there's a "right answer", it will be in the final version
of the notes online.)

Slide 13

Minute Essay

• Here is one way:

```
/**
  * Compute and add one month's interest.
  */
public void addInterest() {
      balance += (balance * interestRate);
}
```
