$\operatorname{CSCI}\ 3294$ January 30, 2008

Administrivia

- Reminder: Homework 1 due Monday.
- FYI: Minute essay answers will be on final version of notes on Web.

Slide 1

Basic Organization / Terminology

- Kernel heart of operating system, manages processes and files and so forth.
- Shell program that interprets what you enter, calls ("launches") other programs.

This being UNIX, there are several, mostly offering similar functionality but maybe with different syntax.

Several ways to start a shell — next slide.

• Graphical environments, window managers, etc. Also several of these!

Starting a Shell

• From the console, type control-alt-Fn, where n is 1, 2, ... 6, and log in. (To get back to the graphical virtual console, control-alt-F7.)

From a graphical environment, start a "terminal emulator" (xterm, gterm, etc.). If your desktop has a taskbar, might be good to put a "start a terminal" icon on it. (For GNOME, right click on taskbar, then "add to panel", "launcher from menu", etc.)

- From a Windows system, run putty.
- Other ways (log in remotely with ssh, ...)

A Little About Shells

- Several choices; most commonly used are probably bash and tcsh. By default, you get the one in your entry in the password file.
- How to find out what that is? echo \$SHELL. (This displays the environment variable SHELL. More about those later.)
- How to change? chsh command on some systems; on others, can only be changed by administrator.

Or start a different one by typing its name, like any other command.

• Following discussion is about bash, but many other shells offer similar functionality.

Slide 3

What Your Shell Does With What You Type

• Shell provides in-place editing (arrow and other keys), command history, tab completion of filenames, etc. — until you press "return".

- Shell then processes command line expands wildcards and references to variables, "tokenizes" command into commandname and parameters.
- Shell then either processes command (if a builtin), or locates executable in "search path" (PATH environment variable) and forks off a new process.
- Command's return code then available via shell variable.
- (Aside: Wonder what a simple shell program looks like? Look at first homework from my CSCI 4320 last fall!)

What bash Does With What You Type — In-Place Editing

- Simple editing left and right arrows; ctrl-a, ctrl-e, etc.
- Command history move forward/back with up and down arrows, search with ctrl-r.
- Tab completion for filenames, command names, etc.
- Read about bash and/or readline man and info pages for more info.

Slide 5

What bash Does With What You Type — Processing Command Line

 Shell takes completed line and expands filename wildcards, references to variables (more about both in next slides), "tokenizes" command into commandname and parameters, splitting (by default) at whitespace.

Slide 7

If that's not what you want — e.g., to include a space in a filename, inhibit
expansion of filename wildcards, etc. — use escape character (backslash) or
quotes. Single quotes inhibit all of this, double quotes all but variable
substitution.

What bash Does With What You Type — Processing Command Line

- Shell locates command. Two cases:
 - Builtin command shell executes directly.
 - External command shell finds an executable by looking in "search path"
 (PATH environment variable) and forks off a new process.

(Why the distinction? Some things can't reasonably by done in a new ("child") process!)

Command's return code then available via shell variable.
 (Why would anyone care? Useful in writing scripts.)
 (Where does the return code come from? whatever is returned by program — e.g., from C program's main.)

What bash Does With What You Type — Miscellaneous

 Notice that some keys have meanings other than what Windows users are used to — ctrl-C, ctrl-D, ctrl-Z, possibly also ctrl-S, ctrl-Q (depending on environment — e.g., which terminal emulator).

Slide 9

Environment Variables

- Associated with a process (e.g., a shell) there can be "environment variables".
 Useful as another way (in addition to command-line arguments, input from file/keyboard, etc.) of giving process information.
- Some variables of interest PATH, SHELL, HOME, USER.
- To display current value, printenv FOO or echo \$FOO.
- To set value, FOO=value (no spaces) in bash.
- To make value available to other commands, export FOO.

Filename Expansion

 You probably already know about using * as a wildcard for specifying one or more files. Other options too — "filename expansion" section in full bash manual or info pages.

 $\bullet\,$ echo can be used to check what a particular expression expands to.

Slide 11

Minute Essay

• How is the pace of the class so far? too fast (too much new-to-you info), too slow (too little new-to-you info), ...?
