

Fresources "Resource" is anything that should be used by only one process at a time — hardware device, piece of information (e.g., database record), etc. Can be unique (e.g., particular database record) or non-unique (e.g., one block of a fixed-size disk area such as swap space). Slide 4 Preemptible versus non-preemptible — preemptible resources can be taken away from current owner without causing something to fail (e.g., memory); non-preemptible resources can't (e.g., hardware device). Normal sequence for using a resource — request it, use it, release it. If not available when requested, block or busy-wait. Can easily implement this using semaphores, but then deadlock is possible if processes aren't disciplined.

What To Do About Deadlocks - Nothing

- One strategy for dealing with deadlocks "ostrich algorithm" (ignore potential for deadlocks, hope they don't happen).
- Does this work?

What To Do About Deadlocks — Avoidance

- Can base on idea of "safe" states (in which it's possible to schedule to avoid deadlock) versus "unsafe" states (in which it's not). Idea is to avoid unsafe states. (Details in textbook.)
- "Banker's algorithm" (Dijkstra, 1965) idea is to never satisfy request for resource if it leads to unsafe state. (Details in textbook.)
- Does this work?

Slide 16

Memory Management — Preview One job of operating system is to "manage memory" — assign sections of main memory to processes, keep track of who has what, protect processes' memory from other processes. As with CPU scheduling, we'll look at several schemes, starting with the very simple. For each scheme, think about how well it solves the problem, how it compares to others. As with processes, there's a tradeoff between simplicity and providing a nice abstraction to user programs.
