Administrivia

• Reminder: Homework 4 due Monday. You should get *some* performance from multithreading, but it's unlikely to be as good as for some other assignments.

Slide 1

Review — Organization of Our Pattern Language

- Finding Concurrency patterns how to decompose problems, analyze decomposition.
- Algorithm Structure patterns high-level program structures.
- Supporting Structure patterns program structures (e.g., SPMD, fork/join), data structures (e.g., distributed array).
- Implementation Mechanisms no patterns, but generic discussion of "building blocks" provided by programming environments.

Recap of Examples — Algorithm Structure Patterns

- Task Parallelism: numerical integration, Mandelbrot; Homework 2.
- Geometric Decomposition: heat diffusion, matrix multiplication (notice that the way they share data is fairly different); Homework 3.

• Divide And Conquer: mergesort; Homework 4.

Slide 3

Recap of Examples — Supporting Structures Patterns

- Loop Parallelism: most OpenMP examples.
- SPMD all the MPI examples, the "SPMD-style" examples.
- Master/Worker: generic master/worker.

• Distributed Array: the MPI versions of heat diffusion, matrix multiplication.

Implementation Mechanisms Design Space

• We talked early in the semester about nuts and bolts of four specific programming environments.

- Recap that in a more general way as a discussion of "implementation mechanisms". Why do this? good review, and also background if (when?) you later want to learn other parallel programming languages/libraries.
- Think about learning a new procedural language: You ask how to write assignments, if/then/else, loops, etc.
- Are there there analogous "building blocks" for parallel programming? we say there are ...

Parallel Programming Basics

- UE management.
- Synchronization.
- Communication.

• (These may need to be reworked to apply well to OpenCL. Open question for Slide 6 now.)

UE Management

"UE"? In MPI we have processes. In OpenMP we have (implicit) threads. In
Java we have threads. In OpenCL we have — not clear, but I say something
related to work groups. Common theme — something that carries out
computations. Generally have several of these running concurrently. Our
generic term — "unit of execution" (UE).

Slide 7

- In general, what you want to know is how these are created and destroyed.
- Discuss separately for processes and threads ... (Here and in the remaining discussion, I'll omit OpenCL because it's not clear how it fits into the overall scheme.)

Managing Threads

- Threads typically lightweight, so creating/destroying them during computation is reasonable (though one wouldn't want to go overboard). What you want to know is how threads are created, destroyed.
- In OpenMP, threads created by parallel pragma (which applies to a
 "structured block"). All but master thread end and are destroyed at end of
 block to which pragma applies. (Actually, implementation may reuse them for
 subsequent parallel block. But it's as if they're created new each time.)
- In Java, threads created by creating instances of Thread class, or subclass. Must also invoke start. A thread terminates when its run method ends; it's destroyed by the garbage collector in the usual way. java.util.concurrent provides interfaces/classes that hide some of these details.

Managing Processes

 Processes are "heavier" than threads, so creating and destroying them during computation isn't done much. Again, though, what you want to know is how they're created, how they're destroyed.

• In MPI 2.x and later, can explicitly "spawn" a process.

Slide 9

- In MPI 1.1, creating processes is external to the API. Why? Historical reasons, basically. Processes end when the code they run terminates.
 Possible for them to hang around ("orphan processes") if code doesn't end cleanly.
- In Java, there's some support for creating processes, but it's mostly for interfacing with underlying system. Support for distributed-memory computing is via sockets (low-level version of message-passing, in a way) and RMI.

Synchronization

- "Synchronization" very generic term, idea is to enforce constraints on order in which things execute in different UEs. Examples:
 - If one thread holds a particular lock, all other threads wanting the lock must wait.
 - A process executing a blocking "receive a message" operation must wait until the message arrives (which implies that it's been sent, etc.).
- Different systems/environments provide different ways of doing this locks, message-passing, other "synchronization mechanisms" discussed in operating systems courses/texts (semaphores, monitors, etc.). What you want to know, when learning a new language/library, is what it provides along these lines. Look at categories of mostly-commonly-needed functionality . . .

Memory Synchronization and Fences

• Additional complication in shared-memory systems:

In the simple classical model of how things work, reads/writes to memory are "atomic" (execute without interference from other UEs).

Reality these days is somewhat different — hardware may cache values, compiler may do interesting optimizations, etc., etc.

- How to know when there's a consistent view of memory all UEs share?
 "Memory fence" idea writes before the fence visible to reads after it, etc.
- Memory fences usually implicit in higher-level constructs, but you could need
 to know about them if threads share variables that change during execution,
 and access to the variable isn't controlled by some sort of synchronization
 (OpenMP critical section, Java synchronized block, etc.).
- More details in chapter 6, with examples ...

Barriers

- Idea is much like what you might guess from the name point that all UEs must reach before any can proceed.
- MPI has MPI_Barrier function all processes (or all in a
 "communicator" group) call it, and then the ones that arrive early wait until all
 have arrived. Mostly useful in timing things.
- OpenMP has explicit barrier pragma and also inserts implicit barriers at ends of many constructs. (Something to check: single does, while master does not.)
- In early releases of Java, if you wanted a barrier you had to construct one.

 Java 1.5 added java.util.concurrent, whichh includes

 CyclicBarrier, etc.

Slide 11

Mutual Exclusion

Idea is again what you might guess from the name, and as we've discussed
 — only one UE at a time can have access to some "critical section" of code (to prevent "race conditions"). Shared Data talks more about when this is needed.

Slide 13

• OpenMP has critical section pragma. If more flexibility needed, locks also available. (Idea is that before entering a critical section you obtain the relevant lock, and then release it on exit.)

Mutual Exclusion, Continued

 Java has synchronized methods/blocks. Synchronization is with regard to some particular object — and of course, if you want to ensure mutual exclusion, all participating threads must synchronize on the same object. (Beginners often seem to get this wrong!)

Slide 14

MPI doesn't provide explicit functions/constructs for mutual exclusion —
generally no need to manage shared resources because there aren't any. If
needed, "roll your own" — assign all operations on shared resource to a
single process, implement some sort of token scheme, etc.

Communication

• In the shared-memory model, communication (sharing information) among UEs is easy (trivial, really) but synchronization is difficult.

- In the distributed-memory model, other way around.
- Look at two basic categories of functionality . . .

Slide 15

Message Passing

- Basic ideas as discussed earlier idea is that UEs communicate by "sending messages", each with a sender and a receiver and containing any desired data.
- MPI provides explicit support through library functions, as discussed earlier.

- OpenMP doesn't, of course and yet in some cases it can make sense, and it's not hard to "fake it" by using shared variables as buffers. Examples in book.
- Java also doesn't explicitly support message passing, exactly, but
 java.net and java.io packages provide support for communication
 over sockets, and RMI allows a program running on one computer to invoke
 methods on another (with parameters and return values communicated as
 necessary). java.nio package may also be of interest allows one
 thread to monitor multiple connections (previously required multiple threads).

Collective Communication

Basic idea as discussed earlier — communication events that involve more
than two UEs. Frequently all UEs involved. Common examples: broadcast,
barrier, reduction. (Review — reduction means repeatedly applying a binary
operator to "reduce" a set of data items to a single data item. Examples
include sum, product, max, min.)

Slide 17

- MPI provides explicit support through library functions, as discussed earlier.
- OpenMP also provides explicit support for some collective operations, also as discussed earlier — barriers, reduction via reduction clause.
- Java doesn't (as far as I know), but these operations can all be coded in terms
 of point-to-point message passing.
- As an example of "roll your own" discussion of various ways to implement reduction.

Other Communication Constructs

- "One-sided" communication two UEs communicate, but only one of them
 explicitly does anything (e.g., one UE puts something into a buffer on another
 node).
- Various schemes for "virtual shared memory" e.g., "tuple space" in Linda.

Minute Essay

• We only have three full class periods left, plus the last one (when we'll need to do evaluations). How to use them?

I have a few more examples using the programming environments we've seen

 an OpenCL version of the heat diffusion example for one. I think I also have examples of Java using sockets and/or RMI.

- I have examples of a few other programming environments (Pthreads, C++11 threads).
- Other suggestions? I'd like to talk about how what we've done relates to Scala's "actors" model and "futures" concepet but not clear I'll have time to prepare.
- Anyone not planning to be here Monday?
