Boolean Expressions and Functions

9-14-2011

Opening Discussion

- Do you have any questions about the quiz?
- Minute essay comments
 - Roller skating class does allow in-line.
 - The joy of programming and the agony of silly errors.
 - Tabbing in and making tabs small.
 - Putting things into your web space.
 - Bias and mantissa.
 - Are there limits for conditionals/Booleans?
- Let's finish what we were doing last class.

Motivation

- I want to have a function that tells me if two squares intersect.
- The function will be given the x and y location of the center of each square as well as the length of the side of each square.
- It should return a Boolean telling if they intersect.

Conditional Logic

- We talked about comparisons of values in the last class.
- We can also combine Boolean expressions together using Boolean logic.
- There are four Boolean operators:
 - && for and
 - | for inclusive or
 - ^ for exclusive or
 - ! for not

Short Circuit Operators

- The && and || operators are short circuit operators.
- This means that if the value is known after evaluating the first operand, the second operand won't be evaluated.
- This can prevent errors.
- Let's look at an example of this with division by zero.

Nesting ifs

- What you put in an if can be any expression or statement.
- As a result, you can put an if inside of another if.
- As we will see, Scala doesn't care what you nest inside of things. You write the logic that makes sense to you and says what you want to say.

Functions in Math

- Let's review the concept of functions from math.
- In algebra a function would take one or more values and give you back a value. The values were generally numbers.
- In higher level math this is generalized with things like sets.
- In math functions the same input always leads to the same result.

Functions in Programming

- The concept of a function is critically important to programming.
- Functions can take one or more arguments and give us back values. (Most languages allow only one return value.)
- Let's think of some examples of functions that we could write.

Functions in Scala

- We declare functions in Scala using def. Here is the general form.
 - def name(arg1:Type1, arg2:Type2, ...):Type = expression
- The argument list can have zero or more elements. If there are zero even the parentheses can be left off.
- Function arguments must have types.
- The return type is optional, but it is recommended.

Why Functions?

- Functions are used in programs for a number of reasons.
 - Reduce code duplication. You can call the same function multiple times and only write it once.
 - Improve readability and maintainability. Good function names make it easier to read. Small functions are easier to test and debug.
 - Break problems down/problem decomposition.

Problem Decomposition

- Never solve a hard problem. If a problem is hard, break it into smaller problems that are easier. Repeat until you are only solving trivial problems.
- Top-down
 - This is the "normal" approach where you start with the full problem and break it into pieces.
- Bottom-up
 - Sometimes you realize that different trivial pieces will be useful and build up from those.

Minute Essay

- What are your thoughts so far on the book? Have you been reading? How much is it helping?
- Remember, there is no class on Friday for the campus wide curriculum discussion.
