

# Parsing Output

11-7-2011

# Opening Discussion

- Minute essay comments:
  - Parsing HTML with a CF grammar.

# Example CF Grammar

- Here is a CF grammar for math expressions:
  - $\text{expr} ::= \text{term} \{ \text{"+" term} \mid \text{"-"} \text{term} \}$
  - $\text{term} ::= \text{factor} \{ \text{"*"} \text{factor} \mid \text{" /"} \text{factor} \}$
  - $\text{factor} ::= \text{floatingPointNumber} \mid \text{"(" expr ")"}$
- Use  $\{ \}$  for 0 or more and  $[ ]$  for 0 or 1.
- Lots of languages here:
  - <http://wwwantlr.org/grammar/list>

# Scala Parsers

- `import scala.util.parsing.combinator._`
- `class Arith extends JavaTokenParsers {`
  - `def expr:Parser[Any] = term~rep("+~term | -~term)`
  - `def term:Parser[Any] = factor~rep("*~factor | /~factor)`
  - `def factor:Parser[Any] = floatingPointNumber | ("~expr~")`
- `}`

# Conversion Rules

- Put in a class that extends one of the Parsers.
  - Productions become methods.
  - Results are Parsers. Next class we'll see how to make it more specific than Any.
  - Consecutive symbols are adjoined with  $\sim$ .
  - The  $\{\dots\}$  is replaced with `rep(...)`.
  - The  $[\dots]$  is replaced with `opt(...)`.

# Using the Parser

- Call `parseAll` or `parse` on your class.
- Takes two arguments:
  - First argument is the parser to use.
  - Second argument is the string to parse.
- Let's code this all up and see it in action.

# Default Parser Output

- Strings match themselves.
- RegEx and tokens give strings.
- $P \sim Q$  gives back  $\sim(p, q)$ , where  $p$  and  $q$  are the matches of  $P$  and  $Q$ .
- $P \mid Q$  gives either  $p$  or  $q$ .
- $\text{rep}(P)$  or  $\text{repsep}(P, \text{seperator})$  give a list of  $p$  values.
- $\text{opt}(P)$  gives an Option, either  $\text{Some}(p)$  or  $\text{None}$ .

# Specifying Output

- You can override the default of  $P$  by using  $P \wedge\wedge f$ . The  $f$  is a function (or partial function) that takes the normal output of  $P$ .
- The output you get is  $f(p)$ .
- Example uses:
  - `floatingPointNumber  $\wedge\wedge$  (_.toDouble)`
  - `“true”  $\wedge\wedge$  (x=>true)`
  - `“(“~ident~”, “~ident~”)”  $\wedge\wedge$  { case  
““(“~i1~”, “~i2~”)” => (i1,i2) }`

# Ignoring Parts of the Parse

- In something like the last example shown, there are strings that are part of the parse that really don't impact the result.
- When you have this type of situation you can use  $\sim>$  or  $<\sim$  instead of just  $\sim$ . The parse result will only include what the arrow points to.
  - “(“ $\sim>$ ident $\sim$ ”, “ $\sim$ ident $<\sim$ ”)” ^^ { case i1 $\sim$ ”, “ $\sim$ i2  
=> (i1,i2) }

# Our Code

- Let's work on putting this type of functionality in our formula code.
- We want to parse to a tree similar to what we produced with the recursive parser we wrote ourselves.
- With that we can make this alternate code functional.

# Minute Essay

- What questions do you have about parsers, regex, or grammars?
- Next class we do spatial trees.
- IcP #7 is next class.
